Abstract

The ground and P -wave excited states of nnn , nns and ssn baryons are studied in the framework of the field correlator method using the running strong coupling constant in the Coulomb-like part of the three-quark potential. The running coupling is calculated up to two loops in the background perturbation theory. The three-quark problem has been solved using the hyperspherical functions method. The masses of the S - and P -wave baryons are presented. Our approach reproduces and improves the previous results for the baryon masses obtained for the freezing value of the coupling constant. The string correction for the confinement potential of the orbitally excited baryons, which is the leading contribution of the proper inertia of the rotating strings, is estimated.

1 Introduction

Quantum chromodynamics (QCD) has been established as the theory describing the strong interaction but its application to low-energy hadron phenomenology is still far from a routine deduction. Various approximations, whose connection to the underlying theory remains sometimes obscure, are presently used to describe baryon spectroscopy. There is a vast literature of theoretical treatment of baryons, including treatment in specific quark models [1], QCD sum rules [2], effective field theories [3], the Skyrme model [4], the collective models of the baryon such as the algebraic approach of Ref. [5], and large N_c analysis [6], as well as on the lattice [7]. It has become an attractive program to develop model independent methods which are firmly based in fundamental theory. In particular, ground state spectroscopy in lattice QCD calculations appears to be well understood [8]. Excited state spectroscopy on the lattice, however, is still a challenging task [9].

The field correlator method (FCM) in QCD [10] provides another perspective. The FCM is a promising formulation of the nonperturbative QCD that gives additional support to the quark model assumptions. Progress was recently made [11]–[14] towards placing the computation of baryon masses within the FCM on the same level as that of mesons [15]. Nevertheless, this work can be refined. In Refs. [11]–[14] a freezing value of the strong coupling constant in the perturbative Coulomb-like potential has been employed. This choice appears to be a reasonable approximation and gives rise to a good description of heavy quarkonia [16] and heavy-light mesons [17]. Note that within QCD most of the baryon mass is produced by quark confinement. For light baryons the Coulomb-like force does not play a crucial role and produces only a marginal ($\sim 10\%$) correction [11]. Nevertheless, it is important to include into the FCM approach the modern knowledge about the one-gluon exchange forces that still represent a fundamental concept which might give us a deeper understanding of baryon spectroscopy [18].

The objective of this paper is to explore the FCM for baryons in a more regular way by considering the effects of the running strong coupling constant in the Coulomb-like part of the three-quark potential. We use the background perturbation theory (BPTh) [19] for the coupling constant to avoid the infrared singularities. Below are considered the baryons composed of valence light quarks, the *up*, *down*, and *strange* flavors. We present the new results for the masses of the ground states and P -wave excited states of nnn , nns and ssn baryons. We also for the first time estimate the string correction to the baryonic orbital excitations. So far, this correction was calculated for the orbitally excited mesons [20], [17] and hybrid charmonium states [21].

This paper is organized as follows. In Sec. 2, we give a brief summary of the effective Hamiltonian (EH) method important for our particular calculation¹. In Sec. 3, we discuss the calculation of the string

¹The application of this method for the baryons was described in detail elsewhere [11, 12, 14].

correction. In Sect. 4, we use BPTh for the strong coupling constant to define the Coulomb-like potentials. A brief description of the hyperspherical approach, which is a very effective numerical tool for solving the three-quark problem is given in Sect. 5. Our results for the masses of the nnn , nns and ssn baryons including comparison to the previous ones obtained within the FCM with a freezing value of the strong coupling constant are presented in Sec. 6. The concluding remarks follow in Sec. 7.

2 Effective Hamiltonian in FCM

In the FCM three-quark dynamics in a baryon is encoded in gluonic field correlators which are responsible for quark confinement. Starting from the Feynman-Schwinger representation for the quark and gluon propagators in the external field, one can extract hadronic Green's functions and calculate the baryon spectra. The QCD string model corresponds to the limit of a small gluonic correlation length of field correlators.

The key ingredient of the FCM is the use of the auxiliary fields (AF) initially introduced in order to get rid of the square roots appearing in the relativistic Hamiltonian. Historically the AF formalism was first introduced in Ref. [22] to treat the kinematics of the relativistic spinless particles. Using the AF formalism allows one to derive a simple local form of the EH for the three-quark system², which comprises both confinement and relativistic effects, and contains only universal parameters: the string tension σ , the strong coupling constant α_s , and the bare (current) quark masses m_i . In this paper, we do not consider the spin-dependent part of the EH³. Then the EH has the form

$$H = \sum_{i=1}^3 \left(\frac{m_i^2}{2\mu_i} + \frac{\mu_i}{2} \right) + H_0 + V. \quad (1)$$

In Eq. (1) H_0 is the nonrelativistic kinetic energy operator for the constant AF μ_i , the spin-independent potential V is the sum of the string potential

$$V_Y(\mathbf{r}_1, \mathbf{r}_2, \mathbf{r}_3) = \sigma r_{min}, \quad (2)$$

with r_{min} being the minimal string length corresponding to the Y-shaped configuration, and a Coulomb interaction term

$$V_C(\mathbf{r}_1, \mathbf{r}_2, \mathbf{r}_3) = \sum_{i<j} V_C(r_{ij}), \quad (3)$$

arising from the one-gluon exchange.

The EH depends explicitly on both bare quark masses m_i and the constants AF μ_i that finally acquire the meaning of the dynamical quark masses. As the first step the eigenvalue problem is solved for each set of μ_i ; then one has to minimize $\langle H \rangle$ with respect to μ_i . Although being formally simpler the EH is equivalent to the relativistic Hamiltonian up to elimination of AF [14].

The formalism allows for a very transparent interpretation of AF μ_i : starting from bare quark masses m_i , we arrive at the dynamical masses μ_i that appear due to the interaction and can be treated as the dynamical masses of constituent quarks. Therefore the constituent quark masses appear in the FCM calculations. These have obvious quark model analogs, but are derived directly using the AF formalism. Due to confinement $\mu_i \sim \sqrt{\sigma} \sim 400$ MeV or higher, even for the massless current quarks.

The baryon mass is given by

$$M_B = M_0 + \Delta M_{\text{string}} + C, \quad (4)$$

$$M_0 = \sum_{i=1}^3 \left(\frac{m_i^2}{2\mu_i} + \frac{\mu_i}{2} \right) + E_0(\mu_i) \quad (5)$$

where $E_0(\mu_i)$ is an eigenvalue of the Schrödinger operator $H_0 + V$, and the μ_i are defined by minimization condition

$$\frac{\partial M_0(m_i, \mu_i)}{\partial \mu_i} = 0. \quad (6)$$

²See Ref. [23]; for a brief review of the EH formalism relevant to the baryon problem considered in this paper see Sec. II of Ref. [11]

³The spin-dependent effects for

baryons within the FCM will be considered elsewhere. For the recent review of spin-dependent interactions in quarkonia in the framework the FCM see [24].

The right-hand side of Eq. (4) contains the perturbative quark self-energy correction C that is created by the color magnetic moment of a quark propagating through the vacuum background field [25]. This correction adds an overall negative constant to the hadron masses:

$$C = -\frac{2\sigma}{\pi} \sum_i \frac{\eta(t_i)}{\mu_i}, \quad t_i = m_i/T_g, \quad (7)$$

where $1/T_g$ is the above mentioned gluonic correlation length. The numerical factor $\eta(t)$ arises from the evaluation of the integral

$$\eta(t) = t \int_0^\infty z^2 K_1(tz) e^{-z} dz, \quad (8)$$

where K_1 is the McDonald function. In what follows we use $T_g = 1$ GeV. Finally, ΔM_{string} in Eq. (4) is the so-called string correction to be discussed in the next section.

The above ingredients provide the basic mechanism that determines the baryon spectrum in the FCM.

3 The string correction

The string potential $V_Y(\mathbf{r}_1, \mathbf{r}_2, \mathbf{r}_3)$ in Eq. (2) represents only the leading term in the expansion of the QCD string Hamiltonian in terms of angular velocities [20]. The leading correction in this expansion is known as a string correction. This is the correction totally missing in relativistic equations with local potentials. Its sign is negative, so the contribution of the string correction lowers the energy of the system, thus giving a negative contribution to the masses of orbitally excited states, leaving the S-wave states intact.

As was mentioned in the introduction, so far, the string correction was calculated only for the orbitally excited heavy-light mesons [17] and hybrid charmonium states [21]. For a baryon with the genuine string junction point the calculation of the string correction is a very cumbersome problem. The calculations are greatly simplified, however, if the string junction point is chosen to coincide with the center-of-mass coordinate $\mathbf{R}_{cm}$. In this case, the complicated string junction potential is approximated by a sum of the one-body confining potentials. The accuracy of this approximation for the P -wave baryon states is better than 1% [14]. Letting $\mathbf{R}_{cm} = 0$ we arrive at the following form of the string potential

$$V_{\text{string}}^{\text{CM}} = \sigma \sum_i |\mathbf{r}_i| \int_0^1 d\beta \sqrt{1 - \mathbf{l}_i^2}, \quad (9)$$

where

$$\mathbf{l}_i = \frac{\beta}{|\mathbf{r}_i|} [\mathbf{r}_i \times \dot{\mathbf{r}}_i] = \frac{\beta}{\mu_i |\mathbf{r}_i|} [\mathbf{r}_i \times \mathbf{p}_i] = -i \frac{\beta}{\mu_i |\mathbf{r}_i|} [\mathbf{r}_i \times \nabla_i]. \quad (10)$$

Expanding the square roots in Eq. (9) in powers of the angular velocities $\mathbf{l}_i^2$ and keeping only the first two terms in this expansion, one obtains

$$V_{\text{string}}^{\text{CM}} \approx \sigma \sum_i |\mathbf{r}_i| \int_0^1 d\beta \left(1 - \frac{1}{2} \mathbf{l}_i^2\right) = \sigma \sum_i |\mathbf{r}_i| + \frac{\sigma}{6} \sum_i \left(\frac{1}{\mu_i^2 |\mathbf{r}_i|} (\mathbf{r}_i \times \nabla_i)^2 \right) \quad (11)$$

and

$$\Delta M_{\text{string}} = -\frac{\sigma}{6} \langle \Psi | \sum_i \frac{(\mathbf{r}_i \times \mathbf{p}_i)^2}{\mu_i^2 r_i} | \Psi \rangle, \quad (12)$$

where Ψ is an eigenfunction of the Hamiltonian (1). Further details and numerical results are given in Sec. 6.

4 Coulomb-like interaction in the BPT_h

As was mentioned above, the spin-independent potential in Eq. (1) is the sum of the confinement potential and Coulomb-like interaction. Details of our treatment of the string junction confinement potential can be

found in the appendix of Ref. [12]. Let us now concentrate on the Coulomb-like part of interaction, $V_C(r)$. It is convenient to write the Coulomb-like potential in QCD in momentum space as

$$V_C(\mathbf{q}^2) = -C_F \frac{\alpha_V(\mathbf{q}^2)}{\mathbf{q}^2}, \quad (13)$$

where C_F is the color factor. In a baryon, the two quarks belong to the representation $\bar{\mathbf{3}}$ of $SU_c(3)$ for which $C_F = 2/3$. A running constant $\alpha_V(\mathbf{q}^2)$ controls the behavior of standard perturbation theory (SPTh) at low momentum scales. The formal expression for $V_C(r)$ in position space can be written as

$$V_C(r) = -C_F \frac{\alpha_s(r)}{r}, \quad (14)$$

where

$$\alpha_s(r) = \frac{2}{\pi} \int_0^\infty dq \frac{\sin qr}{q} \alpha_V(\mathbf{q}^2). \quad (15)$$

Up to two loops

$$\alpha_V(\mathbf{q}^2) = \frac{4\pi}{\beta_0 t} \left(1 - \frac{\beta_1}{\beta_0^2} \frac{\ln t}{t} \right), \quad (16)$$

where β_i are the coefficients of the QCD β -function,

$$\beta_0 = 11 - \frac{2}{3}n_f, \quad \beta_1 = 102 - \frac{38}{3}n_f, \quad (17)$$

and

$$t = \ln \frac{\mathbf{q}^2}{\Lambda_V^2} \quad (18)$$

In what follows we use $n_f = 3$.

The conventional coupling (16) is analytically singular at a scale $\mathbf{q}^2 = \Lambda_V^2$, so the SPTh itself is not well defined in the infrared domain where the coupling become large. This problem can be traced back to the fact that the integral over the running coupling which appears in Eq.(15) is ill defined. As a result, $\alpha_s(r)$ is known only in the perturbative region, $r \lesssim 0.1$ fm. Estimates of the average interquark distances in light baryons are in the vicinity of 0.7 fm which is certainly outside of the perturbative region.

There also exists the possibility of defining a running coupling which stays finite in the infrared. One such example is the “timelike” effective coupling which is used in the dispersive approach [26]. The idea is that such a coupling may give an effective measure of interaction at low scale [27]. An alternative procedure is to define the fundamental coupling in QCD from a given physical observable [28]. For our purposes, we find it convenient, as a useful approximation, to define the strong coupling constant $\alpha_B(r)$ in the BPTh [19]. In momentum space,

$$\alpha_B(\mathbf{q}^2) = \alpha_s(\mathbf{q}^2 + m_B^2), \quad (19)$$

where $m_B \sim 1$ GeV is the appropriate mass parameter⁴. The logic behind Eq. (19) is that the perturbative gluon propagator is modified strongly at $q \lesssim m_B$ by the physics of large distances. This result can be conventionally viewed as arising from the interaction of a gluon with background vacuum fields.

We define $\alpha_B(r)$, as well as the Coulomb-like potential in the configuration space via expressions similar to (14) and (15)

$$\alpha_B(r) = \frac{2}{\pi} \int_0^\infty dq \frac{\sin qr}{q} \alpha_B(\mathbf{q}^2), \quad (20)$$

$$V_C(r) = -C_F \frac{\alpha_B(r)}{r}. \quad (21)$$

For $\alpha_B(\mathbf{q}^2)$, we use the two-loop result (16) with the substitution

$$t \rightarrow t_B = \ln \frac{\mathbf{q}^2 + m_B^2}{\Lambda_V^2} \quad (22)$$

⁴ This parameter has the meaning of being the lowest hybrid excitation, $m_B = M(Q\bar{Q}gg) - M(Q\bar{Q}g)$; from comparison with the lattice static potential $m_B \sim 1$ GeV.

The resulting coupling $\alpha_B(\mathbf{q}^2)$ is finite in the infrared, $\mathbf{q}^2 \rightarrow 0$. In the ultraviolet region, $\mathbf{q}^2 \gg m_B^2$ one recovers the SPTh result. In configuration space the background coupling constant $\alpha_B(r)$ exists for all distances and saturates at some critical, or freezing, value for $r \gg 1/m_B$. The specific choice of the parameters in Eq. (22) will be discussed in Sec. 6.

5 Hyperspherical formalism for three-quark systems.

Following our previous analysis [12] we use the hyperspherical method to calculate the masses of the ground and excited hyperon states. The idea of hyperspherical method is to generalize the simplicity of the spherical harmonic expansion for the angular functions of a two particle in three dimensional space to a system of N particles by introducing in a $3N-3$ dimensional space a global length R called the hyperradius, and a set of angles, Ω . In this section, we briefly review the hyperspherical formalism as applied to our specific problem.

Let us introduce in the system of three quarks with dynamical masses μ_i and coordinates $\mathbf{r}_i$ the three-body Jacobi coordinates in the six-dimensional coordinate space as

$$\boldsymbol{\rho}_{ij} = \sqrt{\frac{\mu_{ij}}{\mu_0}} (\mathbf{r}_i - \mathbf{r}_j), \quad \boldsymbol{\lambda}_{ij} = \sqrt{\frac{\mu_{ij,k}}{\mu_0}} \left(\frac{\mu_i \mathbf{r}_i + \mu_j \mathbf{r}_j}{\mu_i + \mu_j} - \mathbf{r}_k \right), \quad (23)$$

(i, j, k cyclic), where μ_{ij} and $\mu_{ij,k}$ are the reduced dynamical quark masses:

$$\mu_{ij} = \frac{\mu_i \mu_j}{\mu_i + \mu_j}, \quad \mu_{ij,k} = \frac{(\mu_i + \mu_j) \mu_k}{\mu_i + \mu_j + \mu_k}, \quad (24)$$

and μ_0 is an arbitrary parameter with the dimension of mass, which drops out in the final expressions. The baryon wave function depends on the Jacobi coordinates (23). Now we switch from Jacobi coordinates to hyperspherical coordinates in coordinate space

$$R^2 = \boldsymbol{\rho}^2 + \boldsymbol{\lambda}^2, \quad \rho = R \sin \theta, \quad \lambda = R \cos \theta, \quad 0 \leq \theta \leq \pi/2, \quad (25)$$

where R is the six-dimensional hyperradius that is invariant under quark permutations. In what follows we omit the indices i and j .

The explicit expression for the kinetic energy operator H_0 for three-quark systems in the center-of-mass system is remarkably simple in hyperspherical coordinates

$$H_0 = -\frac{1}{2\mu_0} \left(\frac{\partial^2}{\partial R^2} + \frac{5}{R} \frac{\partial}{\partial R} + \frac{\mathbf{L}^2(\Omega)}{R^2} \right). \quad (26)$$

In Eq. (26) Ω denotes the five angular coordinates θ , $\mathbf{n}_\rho$, $\mathbf{n}_\lambda$, and $\mathbf{L}^2(\Omega)$ is a squared hyperangular momentum operator. Its eigenfunctions (the hyperspherical harmonics) are defined by

$$\mathbf{L}^2(\Omega) Y_{[K]}(\theta, \mathbf{n}_\rho, \mathbf{n}_\lambda) = -K(K+4) Y_{[K]}(\theta, \mathbf{n}_\rho, \mathbf{n}_\lambda), \quad (27)$$

with K being the grand orbital momentum.

The wave function $\psi(\boldsymbol{\rho}, \boldsymbol{\lambda})$ is written in a symbolic shorthand notation as

$$\psi(\boldsymbol{\rho}, \boldsymbol{\lambda}) = \sum_{[K]} \psi_{[K]}(R) Y_{[K]}(\Omega), \quad (28)$$

where the set $[K]$ is defined by the orbital momentum of the state and the symmetry properties.

In what follows we use the ansatz $K = K_{\min}$, where $K_{\min} = 0$ for $L = 0$ and $K_{\min} = 1$ for $L = 1$. The accuracy of this approximation has been discussed in [14]. Our task is then extremely simple in principle: we have to choose a zero-order wave function corresponding to the minimal K for a given L . The corresponding hyperspherical harmonics are

$$Y_0 = \sqrt{\frac{1}{\pi^3}}, \quad K = 0, \quad \mathbf{Y}_\rho = \sqrt{\frac{6}{\pi^3}} \frac{\boldsymbol{\rho}}{R}, \quad \mathbf{Y}_\lambda = \sqrt{\frac{6}{\pi^3}} \frac{\boldsymbol{\lambda}}{R}, \quad K = 1. \quad (29)$$

For nns baryons we use the basis in which the strange quark is singled out as quark 3 but in which the nonstrange quarks are still antisymmetrized. In the same way, for the ssn baryon we use the basis in which the nonstrange quark is singled out as quark 3. The nns basis states diagonalize the confinement problem with eigenfunctions that correspond to separate excitations of the nonstrange and strange quarks (ρ - and λ excitations, respectively). In particular, excitation of the λ variable unlike excitation in ρ involves the excitation of the “odd” quark (s for nns or n for ssn). The nonsymmetrized uds and ssq bases usually provide a much simplified picture of the states [33].

For the purpose of implementing our truncation scheme, we introduce the reduced functions $u_\nu(R)$:

$$\Psi_\nu(R, \Omega) = \frac{u_\nu(R)}{R^{5/2}} \cdot Y_\nu(\Omega), \quad (30)$$

where $\nu = 0$ for $L = 0$, and $\nu = \rho, \lambda$ for $L = 1$ ⁵, as well as a new variable

$$x = \sqrt{\mu_0} R = \left(\sum_i \frac{\mu_1 \mu_2}{M} r_{12}^2 + \frac{\mu_2 \mu_3}{M} r_{23}^2 + \frac{\mu_3 \mu_1}{M} r_{31}^2 \right)^{1/2}, \quad (31)$$

that does not depend on μ_o . Inserting Eq. (30) into the Schrödinger equation for $\Psi_\nu(R, \Omega)$ and averaging the interaction $V = V_Y + V_C$ over the six-dimensional sphere Ω with the weight $|Y_\nu|^2$, one obtains the one-dimensional Schrödinger equation for $u_\nu(x)$

$$\frac{d^2 u_\nu(x)}{dx^2} + 2 \left(E_0 - \frac{(K + \frac{3}{2})(K + \frac{5}{2})}{2x^2} - V_Y^\nu(x) - V_C^\nu(x) \right) u_\nu(x) = 0, \quad (32)$$

where

$$V_Y^\nu(x) = \int |Y_\nu(\theta, \chi)|^2 V_Y(\mathbf{r}_1, \mathbf{r}_2, \mathbf{r}_3) d\Omega = \sigma b_\nu x, \quad (33)$$

and

$$V_{\text{Coulomb}}^\nu(x) = -\frac{2}{3} \int |Y_\nu(\theta, \chi)|^2 \sum_{i < j} \frac{\alpha_B(r_{ij})}{r_{ij}} d\Omega = -\frac{2}{3} \frac{a_B^\nu(x)}{x}. \quad (34)$$

The constants b_ν in Eq. (33) are defined by the two-dimensional integrals in the plane ($\theta, \cos \varphi = \hat{\boldsymbol{\rho}} \hat{\boldsymbol{\lambda}}$). Explicit expressions for these integrals are written in the appendix of Ref. [12]. The functions $a_B^\nu(x)$ are

$$a_B^\nu(x) = \sum_{i < j} \sqrt{\mu_{ij}} \int \alpha_B \left(\frac{x \sin \theta}{\sqrt{\mu_{ij}}} \right) \frac{d\omega_\nu}{\sin \theta}, \quad (35)$$

where

$$d\omega_0 = \frac{16}{\pi} \sin^2 \theta \cos^2 \theta d\theta, \quad (36)$$

and

$$d\omega_\rho = \frac{32}{\pi} \sin^4 \theta \cos^2 \theta d\theta, \quad d\omega_\lambda = \frac{32}{\pi} \sin^2 \theta \cos^4 \theta d\theta. \quad (37)$$

6 Results and discussion

In the previous sections, we introduced the Hamiltonian we use to obtain baryon spectra. This Hamiltonian contains five parameters: the current quark masses m_n and m_s , the string tension σ , and two parameters Λ_V and m_B defining $\alpha_B(\mathbf{q}^2)$ in Eq. (22). Let us underline that they are not the fitting parameters. In our calculations we use $\sigma = 0.15 \text{ GeV}^2$ found in the SU(3) QCD lattice simulations [29]. We employ the current light quark masses $m_u = m_d = 7 \text{ MeV}$ and the bare strange quark mass $m_s = 175 \text{ MeV}$ found previously from the fit to D_s spectra [17]. This value of the strange quark mass is consistent with the QCD sum rules estimation $m_s(2 \text{ GeV}) = (125 \pm 40) \text{ MeV}$ [30]. More recent estimation yields

⁵In what follows, for ease of notation we will drop the magnetic quantum numbers of the vector spherical harmonics.

Figure 1: The dependence of the running coupling constant $\alpha_B(r)$ on the distance for $m_B = 1$ GeV and $\Lambda_V = 0.36$ (solid line), 0.38 (dashed line) and 0.34 GeV (dotted-dashed line)

Table 1: The freezing values of $\alpha_B(\infty)$ for the different choices of Λ_V and m_B . The values of Λ_V and m_B are given in GeV.

Λ_V	0.34			0.36			0.38		
m_B	0.95	1.00	1.05	0.95	1.00	1.05	0.95	1.00	1.05
$\alpha_B(\infty)$	0.492	0.467	0.445	0.526	0.496	0.471	0.563	0.528	0.500

$m_s(2 \text{ GeV}) = (90 \pm 10) \text{ MeV}$ [31]. Recall that in our Hamiltonian approach the current mass m_s enters at a much lower scale. For the remaining two parameters Λ_V and m_B in Eq. (22) we employ the values

$$\Lambda_V = (0.36 \pm 0.02) \text{ GeV}, \quad m_B = (1 \pm 0.05) \text{ GeV}, \quad (38)$$

determined previously in Ref. [32]. The result is consistent with the freezing of $\alpha_B(r)$ with a magnitude $\sim 0.5 - 0.6$, see Table 1. The behavior of $\alpha_B(r)$ for $\Lambda_V = 0.36$ GeV is shown in Fig. 1 for three different values of m_B . We use the error bars in Eq. (38) to illustrate the sensitivity of the baryon masses to the chosen input. Note that $\alpha_B(r)$ increases with Λ_V and, for fixed Λ_V , decreases with m_B .

We begin the discussion of our results by examining the predictions for the ground states of the nnn , nns and ssn baryon with $L = 0$. In Table 2 are displayed the nnn , nns and ssn masses for the three choices of Λ_V : 0.34, 0.36 and 0.38 GeV, and three choices of m_B : 0.95, 1.00 and 1.05 GeV. In this table we also show the dynamical masses μ_i found from the minimum condition (6).

The results in Table 2 show that the baryon masses decrease when Λ_V increases and, for fixed Λ_V , the baryon masses decrease when m_B increases. This comes as no surprise: the effect can be easily read off from the results of Table 1 and Fig. 1. Increasing Λ_V for fixed m_B and decreasing m_B for fixed Λ_V leads to increased running constant $\alpha_B(r)$ and respectively, to decreased baryon masses. Upon varying the parameters Λ_V and m_B , we obtain the baryon masses in the interval 1161–1209 MeV (nnn), 1246–1297 MeV (nns), and 1330–1383 MeV (ssn). The difference in the mass values is mostly due to the difference in the running of the strong coupling in the midmomentum regime.

It is instructive to compare the results obtained for the running coupling constant (RCC) with those

Table 2: The masses of the nnn , nns and ssn baryons with $L = 0$. All quantities are given in MeV.

nnn				nns				ssn		
Λ_V	m_B	μ_1	μ_3	M_B	μ_1	μ_3	M_B	μ_1	μ_3	M_B
340	1050	407	407	1209	412	452	1297	457	417	1383
	1000	409	409	1201	414	453	1288	458	419	1373
	950	410	410	1190	415	455	1277	460	421	1363

	1000	411	411	1187	417	456	1276	461	422	1360
	950	414	414	1177	419	458	1263	463	424	1347
380	1050	412	412	1186	418	457	1274	462	423	1358
	1000	414	414	1174	420	459	1252	464	425	1345
	950	417	417	1161	422	461	1246	466	428	1330

obtained for the freezing coupling constant (FCC) $\alpha_s^{(0)} = 0.39$ [12]. In Table 3 such comparison is presented for the S - and P -baryon states for the particular set of the parameters $\Lambda_V = (0.36 \pm 0.02)$ GeV and $m_B = 1$ GeV. In this table we compare the dynamical masses μ_i and the baryon masses $M_0 + C$ in Eq. (4). The quantities shown in the rows labeled by RCC have been calculated for $m_B = 1.00$ GeV, the central results correspond to $\Lambda_V = 0.36$ GeV, the upper error bars correspond to $\Lambda_V = 0.34$ GeV, and the lower error bars correspond to $\Lambda_V = 0.38$ GeV.

From Table 3, it can be seen that for the S -states the baryon masses calculated for the RCC and FCC are all in agreement with each other within the error bars, although the central values for the nnn , nns and ssn states are typically lower by about 20 MeV than those for the FCC. For the P -waves, the central values of the masses of ρ excitations are typically 20 MeV heavier than those for the FCC while the central mass values of the λ excitations are smaller by about 50 MeV than those values calculated for $\alpha_s^{(0)} = 0.39$. Note that introducing the RCC eliminates the degeneracy of the ρ and λ -excitations for the nnn states found previously for the FCC [14].

Now let us consider the string correction for the confinement potential for the orbital excitations. Explicit calculation [34] of the matrix elements in Eq. (12) yields

$$\Delta M_{\text{string}}^\rho = -\frac{64\sigma}{45\pi} \cdot \frac{1}{\mu^{3/2}} \sqrt{\frac{1+\kappa}{2+\kappa}} \gamma_\rho, \quad (39)$$

$$\Delta M_{\text{string}}^\lambda = -\frac{64\sigma}{45\pi} \cdot \frac{\kappa}{\mu^{3/2}(2+\kappa)^{3/2}} \left(\frac{1}{\kappa^{5/2}} + 2\sqrt{1+\kappa} \right) \gamma_\lambda, \quad (40)$$

where $\mu_1 = \mu_2 = \mu$, $\kappa = \mu_3/\mu$,

$$\gamma_\nu = \int_0^\infty \frac{u_\nu^2(x)}{x} dx, \quad \nu = \rho, \lambda, \quad (41)$$

and the wave functions $u_\nu(x)$ are normalized to unity.

The wave function corrections γ_ν in (41) which influence the string correction does not essentially depend on the baryon flavor nor on the type of excitation. *E.g.* for $\Lambda_V = 0.36$ GeV and $m_B = 1$ GeV we

Table 3: Comparison of the baryon masses $M_0 + C$ in Eq. (4) calculated using the RCC $\alpha_B(r)$ without taking into account the string correction with those obtained for the FCC $\alpha_s = 0.39$ from Ref. [14]. The quantities shown in the rows labeled by RCC have been calculated for $\Lambda_V = 360$ MeV, $m_B = 1000$ MeV, the upper error bars correspond to $\Lambda_V = 340$ MeV, and the lower error bars correspond to $\Lambda_V = 380$ MeV. The masses of the baryons and dynamical masses μ_i are given in MeV.

		<i>nnn</i>			<i>nns</i>			<i>ssn</i>

get (in units of $\text{GeV}^{1/2}$)

$$\gamma_\rho = 0.328 (nnn), \quad \gamma_\rho = 0.326 (nns), \quad \gamma_\rho = 0.325 (ssn),$$

and

$$\gamma_\lambda = 0.333 (nnn), \quad \gamma_\lambda = 0.332 (nns), \quad \gamma_\lambda = 0.331 (ssn).$$

The results for the P -wave excitations of the nnn , nns and ssn baryons when are taking into account the string correction along with the values for the string correction itself are shown in Table 4. Analysis of the data shows that string correction does not essentially depend on the baryon flavor nor on the type of excitation. As a result of the weak dependence of the string correction on a baryon flavor and the type of excitation the masses for all considered baryons become smaller by about the same value $\sim 50 - 60$ MeV (see the 6th column of Table 4).

The baryon energies agree reasonably well with the Particle Data Group (PDG) listing particularly if we take into consideration that spin interactions are neglected. For instance, for $L = 0$ we get $\frac{1}{4}(\Lambda + \Sigma + 2\Sigma^*)_{\text{theory}} = 1276_{-30}^{+23}$ MeV, where the error bars correspond to the variation of the hyperon masses within the chosen range of Λ_V and m_B versus $\frac{1}{4}(\Lambda + \Sigma + 2\Sigma^*)_{\text{exp}} = 1267$ MeV. For the Ξ , we have $\Xi_{\text{theory}} = 1360_{-30}^{+23}$ MeV, whereas $\Xi_{\text{exp}} = 1315$ MeV. However, for the nucleon we get $\frac{1}{2}(N + \Delta)_{\text{theory}} = 1187_{-21}^{+22}$ MeV, which is about 100 MeV heavier than $\frac{1}{2}(N + \Delta)_{\text{exp}} = 1085$ MeV. The difference can be ascribed to the effects of spin-dependent quark-quark interactions modeled after the effect of gluon exchange in QCD [35] or arising from one-boson exchange [36] that are completely omitted in the present approach ⁶. Another source of the discrepancy is the systematic error associated with the use of the AF formalism, which is maximal for the S -wave nnn states [14].

⁶Note that the one-boson exchange effects are important for baryons containing the scalar nn diquarks (N and Λ) and much less important for the baryons containing the axial diquarks (Δ and Σ), see *e.g.* Ref. [37].

Table 4: Masses of the ρ and λ baryon excitations for $m_B = 1000$ MeV taking into account the string corrections, Eqs. (39), (40). The masses of the baryons, string corrections and dynamical masses μ_i are given in MeV.

Baryon	Excitation	Λ_V	$\mu_1 = \mu_2$	μ_3	$M_0 + C$	ΔM_{string}	M_B

		0.38	499	516	1756	-51	1705

The physical P -wave states are not pure ρ or λ excitations but linear combinations of all states with a given total momentum J . Most physical states are, however, close to pure ρ or λ states [33]. For example, the masses of $N(1535)$ and $N(1520)$ resonances with $J^P = \frac{1}{2}^-$ and $J^P = \frac{3}{2}^-$, respectively, both match with the mass of the λ -excitation for the nnn baryon from Table 4: $M_\lambda(nnn) = 1567^{+13}_{-14}$ MeV. The masses of $\Sigma(1620)$ and $\Sigma(1670)$ states with $J^P = \frac{1}{2}^-$ and $J^P = \frac{3}{2}^-$, respectively, match very closely with the mass of the λ -excitation for the nns baryon: $M_\lambda(nns) = 1636^{+13}_{-15}$ MeV. The masses of the ρ -excitations which correspond to P -states of the light diquarks are typically 60 - 80 MeV higher.

The comparison of our result for the negative parity ground state in the Ξ channel, $M_\lambda(ssn) = 1720^{+14}_{-15}$ MeV with the other theoretical predictions for this state and the result from the PDG listing is presented in Table 5.

Table 5: Low-lying Ξ spectrum of spin $L = 1$ predicted by the nonrelativistic quark models of Chao, Isgur and Karl [33] and of Pervin and Roberts [38], the relativized quark model of Capstick and Isgur [39], the Glozman-Riska model [36], the large N_c analysis [6], the algebraic model [5], QCD sum rules [40], and the Skyrme model [4]. The question mark in the last column means that the J^P quantum numbers are not identified by PDG. The masses are given in MeV.

7 Conclusions

In this paper the study of the ground and excited states of the qqq , qqs and ssq baryons by including into the EH derived using the FCM the effects of the running strong coupling constant $\alpha_B(r_{ij})$ in the perturbative Coulomb-like part of the three-quark potential is presented. The results have refined our previous studies obtained for the freezing coupling constant. The three-quark problem has been solved using the hyperspherical approach. The string correction for the confinement potential of the orbitally excited baryons is estimated. For each baryon, we have calculated the dynamical quark masses μ_i from Eq. (6) and the baryon masses (4) with the self-energy corrections (7) and the string corrections (39), (40). The main results are given in Tables 2 - 4. Our study shows that a fairly good description of the S and P -wave baryons can be obtained with spin independent energy eigenvalues corresponding to the confining along with Coulomb potentials. We emphasize that no fitting parameter were used in our calculations. This comparative study provides deeper insight into the quark model results for which the constituent masses encode the QCD dynamics.
